What Makes Chicago's Rivers Look Like Chicago? An Ethnographic Study Using Autonomous Boats

Michael Valentino Ochoa (LAST REVISION: 3/6/20)

I.   MOTIVATION

Global sea level rise will be one of the greatest challenges facing our society this century, and understanding how this phenomenon will reverberate onto riverway communities will require a regular presence. Large scale perturbations such as pollution, invasive species and increasing human demands are multidimensional problems. The goal of this study is to develop an autonomous boat with a human ethnographer aboard to better understand this problem.

In this paper we document the hull design, sensor kit and system architecture for an autonomous boat. The boat uses a high definition camera and sensors to generate a detailed portrait of the river that intelligently controls its steering, throttling and braking, on which collective algorithms for lane keeping, obstacle detection, active cruise control and localizing its center of buoyancy can be assessed. The second contribution of this paper is a customer facing business plan that blends old world traditions (Venetian water taxis) and the modern culture that characterizes Chicago (hospitality, delivery systems and autonomous transportation services). The business will make the bulk of its money selling a proprietary autonomous delivery system and its services to cities and business along Chicago's rivers.

This paper is structured as follows:

Section II presents the hull design and sensor kit. Section III draws out the system architecture for the Riverway Awareness and and Warning System (RAWS). Section IV thru X describe RAWS in greater detail. Field testing and results are unpacked in Section XI and Section XII gives way to the discussion. To conclude Section XIII presents the customer facing business plan.

What Makes Chicago's Rivers Look Like Chicago? An Ethnographic Study Using Autonomous Boats

Michael Valentino Ochoa (LAST REVISION: 3/6/20)

II. HULL DESIGN & SENSOR KIT

It's an age old question, should you transport more cargo/people on a slow boat, or less cargo/people on a faster boat. We believe less is best.

To establish the hull's prototype design we use simulation software (Tripp__HullDesign) to guide the design of a low drag hull. To construct the hull (approximately 1:8) we laser cut marine grade plywood and couple it with 3D printed components. Next, within a leak proof housing we add a mini computer, micro controller, wifi adapter and GPS kit with associated software (Tripp__Core, Tripp__Utils, Tripp__Launch). The boat's components are then married together with zip ties and epoxy thickened with wheat flour. Finally a 40 Watt solar panels and thrusters are added to bring our proof of concept to life.

With the hull and body established we add our sensor kit with software drivers consisting of: (1) high definition color camera pointed forward and angled slightly downward for long range vision, (2) 2D LiDAR sensors pointed forward with different tilt angles for vision within 25 meters, (2) thermal radars for distances as far 200 meters, (1) sonar sensor for underwater obstacle detection and (1) Inertial Movement Unit sensor (IMU) which all together help the boat localize itself and its surroundings to centimeter level precision.

Michael Valentino Ochoa (LAST REVISION: 3/6/20)

III. RIVERWAY AWARENESS AND WARNING SYSTEM (RAWS)

Our system architecture, which goes by the name of RAWS generates a detailed image of the riverway. RAWS zeros in on optimizing arbitrary non-linear functions in robotics applications. Applications include: maximizing sensor kit absorption, minimizing energy consumption, computing resting configurations and optimizing the boat's execution time for "Where am I? Where is everyone else? How do I get from A to B?"

The RAWS architecture stretches across seven interconnected layers detailed in sections IV thru X. Lower layers interact with the sensors and actuators to produced desired positioning and tracking performance. While higher layers are used for maneuvering, errors identification and reconfigurations. By decoupling the problem the optimization across seven layers we make the problem more tractable.

Fig. 2. System Architecture (aka RAWS)

Michael Valentino Ochoa (LAST REVISION: 3/6/20)

IV. LOCALIZATION (USING HISTOGRAM FILTERS)

+ Where am I?

Construct a histogram filter and blend it with a real map to localize the boat's position, orientation and velocity using the GPS beacon. The histogram filters reflect the boat's understanding of its current location as a probability distribution. Measurement updates (i.e. sensing) use the Bayes Rule and motion updates (i.e. movement) use the Theorem of Probability.

Tripp__LocalizationHistogram

V. RIVERWAY PERCEPTION

+ Where is everyone else?

Identify "lanes" and classify static obstacles using the boat's front facing camera

Tripp__RiverLaneFinder

VI. DEEPER RIVERWAY PERCEPTION

+ Where is everyone else?

Determine with certainty the location of others with a Kalman Filter for accurate estimation of both static and dynamic obstacles

Tripp__KalmanFilter

VII. WAVE RUGGEDNESS INDEX

+ Where is everyone else?

Set maximum speed based on the shock imparted using IMU sensor

Tripp__WaveRuggednessIndex

VIII. PATH PLANNER

Map the boat's position, orientation and velocity along a pre-planned route by minimizing cost functions for action and terrain

Tripp__PathPlanner

What Makes Chicago's Rivers Look Like Chicago? An Ethnographic Study Using Autonomous Boats

Michael Valentino Ochoa (LAST REVISION: 3/6/20)

IX. BEHAVIORAL CLONING

Train a neural net to drive our autonomous boat like a human

Tripp__BehavioralCloning

X.   STEERING CONTROL

+ How do I get from A to B?

Send steering, throttle and brake commands to boat's thrusters using proportional-integral-derivative (PID) and a model predictive controller. The goal is calculate an open loop optimal control problem and minimize a given objective function while respecting given constraints, and repeatedly solve it to obtain dynamic feedback control laws.

XI. FIELD TESTS & RESULTS

A.   FIELD TESTING SETUP

Establishing repeatable environments for testing is paramount. Our testing ground stretches between the Goose Island Overlook (1100N) and the East Bank Club 571 (200N) along the North Branch of the Chicago River. We've developed a set of tools to simulate, test and evaluate the RAWS system architecture.

B. FIELD TESTS

C. ETHNOGRAPHIC NOTES

D. SAFETY TESTS

E. SUSTAINABILITY TESTS

XII. DISCUSSION & FUTURE RESEARCH

In the paper we extend the capacity of an autonomous robotic boat to understand:

— Where am I?
— Where is everyone else?
— How do I get from A to B?
— What stylistic elements and geo-spatial patterns (i.e. the visual minutiae of daily urban and natural life) make Chicago's Rivers look like Chicago?

We run open water field tests in fog, rain, smoke and dynamic lighting to validate the efficiency and accuracy of the boat's collective algorithms.

Data from the field tests also helps the boat proactively improve its autonomous practices for lane keeping, obstacle avoidance, active cruise control and localizing its center of buoyancy. The goal is to create an experience that could impress both a safety and sustainability commisioner. The long-term goal is for our Greenhouse Gas Emissions (GHGs) to be zero/net positive within the decade.

Future research will explore some of the more challenging problems in autonomous transportation — mapping real physical rivers, as they're something that change fast and are very big. Our research extends Professor Geoffrey Hinton et la.'s research to conceptualize a prefrontal cortex, whose dopamine based architecture stamps in associations between pixel-level sensor data flows. We believe this approach helps the boat better establish its own "rules of thumb" about how to safely and efficiently navigate its preplanned routes with better consideration for scale, obstructions and viewing angles.

XIII. CUSTOMER FACING BUSINESS

A. WHO IS THE CUSTOMER? WHAT PROBLEM DO WE SOLVE FOR THEM?

Through the eyes of customers we're just another option for moving cargo/people. Though what we do different is target city transportation's weaknesses — it's crowded, uncomfortable and un-hospitable during rush hour. We remedy this transportation problem with light heartened human personalities, comfortable seating and a shockingly smooth experience for cargo/people. Our goal is to be a front runner in the emerging riverway transportation experience.

B. HOW HAVE WE VALIDATED THE PROBLEM?

Our business was envisioned to reduce roadway congestion and help riverway communities quickly move cargo/ people. We see Chicago's Riverways almost like a giant express lane slicing thru the city — a lane that's been empty far too long.

To validate the city's transportation problem we developed a 16 item questionnaire to better understand people's perceptions, preferences and attitudes about riverway transportation services. Our survey was tested on 32 respondents across different ages, proximity to the river, method of transportation to river, race, gender and family income level.

C. OUR SOLUTION

We recognize there is an immense amount of noise in the autonomous transportation industry. For years the challenge focused on engineering, but as the technology gets increasingly commodified, trying to build services in a new regulatory environment has become the new challenge.

We will make the bulk of our money selling a proprietary autonomous

What Makes Chicago's Rivers Look Like Chicago? An Ethnographic Study Using Autonomous Boats

Michael Valentino Ochoa (LAST REVISION: 3/6/20)

delivery system and its services to cities and business along the rivers. Our goal is to help make Chicago's Rivers another powerhouse mercantile and transportation hub of the city.

Our solution is a low wake low emission autonomous boat that uses sensors to generate a detailed portrait of the river to intelligently control its steering dynamics. With a human safety driver aboard the boat will be available for 3 roundtrips in the AM, 3 roundtrips in the PM and riverside delivery services throughout the day. Services will be available between the Julia C. Lathrop Homes (2800N) and Park No. 571 (2800S) along the North and South Branches of the Chicago River.

Fig. 4. Conceptual Renderings

D. MAKING THE REGISTER RING

We will make the bulk of our money selling a proprietary autonomous delivery system and its services to cities and business along the riverways.

Services include: (1) moving cargo for a flat rate (2) hospitably transporting people for a flat rate (3) offering buyouts for groups seeking a cannabis inspired tour of the river (4) selling goods abroad our boat.

Michael Valentino Ochoa (LAST REVISION: 3/6/20)

E. WHAT MAKES US UNIQUE?

Our unique approach understands that the hospitality and autonomy world speak different languages. And until someone figures out how to bridge that gap, a full scale vertically integrated riverway transit service is not going to succeed.

Our culture is rooted in empowering a group of self-confident entrepreneurs who work alongside our autonomous boats. Generally speaking, our business believes in letting autonomous boats do what they do best (e.g. lane keeping, obstacle detection, active cruise control) and letting humans aboard the boats do what we do best (e.g. being the clever and hospitable animals we are). We sense a clear market opportunity on the river and hope to incite some newfound sociability around our services that are equal parts home-away-from-home on the river and roving trading post.

F. WHAT KEEP US UP AT NIGHT?

At a time when our generation faces ecological, economic and values crises, some of the best solutions in navigating the path ahead may not be autonomous boats. Technology is not a cure-all solution, but it offers an opportunity to fundamentally redesign systems that better meet the terms of the Paris Climate agreement. Our vision is not necessarily the answer, but rather a step in a creative learning process towards healthier cities :)

APPENDIX B

Software Packages

<u>Tripp__LocalizationHistogram</u>

<u>Tripp__RiverLaneFinder</u>

<u>Tripp__KalmanFilter</u>

<u>Tripp__WaveRuggednessIndex</u>

Isolates the movement caused by choppy open waters with some sophisticated math to establish a wave ruggedness index.

<u>Tripp__PathPlanning</u>

<u>Tripp__BehavioralCloning</u>

<u>Tripp__Autonomy</u>

Establishes suitable control laws for the boat's thrusters using a dopamine based architecture on which collective algorithms for steering angle, throttling and braking can be assessed based on conditions and task

<u>Tripp__HullDesign</u>

Leverages existing software to flush out the design of a low wake omni-directional catamaran inspired hull.

<u>Tripp__Core</u>

Manages sensors, low communication and actuators

<u>Tripp__Utils</u>

Utility scripts for commanding boat from manual override from laptop, configuration files and installer scripts

<u>Tripp__Launch</u>

Expedites task setup by calling packages with configurations

<u>Point__Cloud__Lib</u>

Formatting and processing toolkit for point cloud data

<u>Drivers for Sensors</u>

<u>Robot Operating System (ROS)</u>

High level processing and middleware for robot software development that supports linux
